Problem Statement:

To develop a robust web scraping application using Python to extract data from dynamic websites. The task involves scraping data from three different pages of the website "scrapethissite.com"

Scrapping Link:

1. <https://www.scrapethissite.com/pages/ajax-javascript/#2015>
2. <https://www.scrapethissite.com/pages/forms/>
3. <https://www.scrapethissite.com/pages/advanced/>

Setup and Installation:

Before running the scraping application, ensure that Python 3.x is installed on your system. Additionally, install the following dependencies:

requests
BeautifulSoup
pymongo (for MongoDB)

Installation commands:

- pip install requests
- pip install BeautifulSoup
- pip install pymongo

Create a virtual environment and install the required packages:

```
python -m venv venv  
source venv/bin/activate # On Windows use `venv\Scripts\activate`
```

Technology and Tech Stack Used:

1. Python
2. VSCode IDE
3. MongoDB

Libraries Used:

`requests`: For making HTTP requests to fetch web pages and their content.

`BeautifulSoup`: For parsing HTML and XML documents, facilitating data extraction from web pages.

`concurrent.futures.ThreadPoolExecutor`: Utilized for concurrent execution of scraping scripts, improving performance by executing multiple tasks simultaneously.

`subprocess`: For running external processes, facilitating the execution of scraping scripts from the main script.

`logging`: Used for implementing logging functionality, allowing the application to log errors and messages to a file for debugging purposes.

`pymongo`: For interacting with MongoDB database, enabling data insertion and manipulation within the database.

`requests.adapters.HTTPAdapter`: For customizing HTTP requests, including setting up retries for handling network errors and timeouts.

`requests.packages.urllib3.util.retry.Retry`: Used with `HTTPAdapter` for defining retry strategies for HTTP requests.

MongoDB Atlas Setup:

1. Sign up/Login to MongoDB Atlas:

Go to the MongoDB Atlas website: [MongoDB Atlas](https://cloud.mongodb.com).
Sign up for an account or log in if you already have one.

2. Create a New Cluster:

Once logged in, click on the "Build a New Cluster" button.
Choose your preferred cloud provider, region, and cluster tier (e.g., M0 Sandbox, M2/M5/M10 shared, or dedicated cluster).
Configure additional settings such as cluster name, disk size, etc., according to your requirements.
Click on the "Create Cluster" button to create your cluster. This process may take a few minutes.

3. Create a Database User:

Go to the "Database Access" tab in the left sidebar.
Click on the "Add New Database User" button.
Enter the username and password for the new database user.
Assign appropriate roles to the user based on your project requirements

4. Connect to Your Cluster:

Once the cluster is created and configured, go to the "Clusters" tab in the left sidebar.
Click on the "Connect" button for your cluster.
Choose the "Connect Your Application" option.
Copy the connection string provided.

5. Update Connection String in Your Project:

Replace the placeholder <username>, <password>, and <clustername> in your MongoDB connection string with the credentials and cluster details obtained from MongoDB Atlas.

Update the connection string in your database.py file with the new MongoDB

Atlas connection string.

Created a database scraperdb

Created 3 collections namely :

1. advanced_data
2. ajax_data
3. forms_data

for 3 websites and storing the scraped data in these collectons.

Output Screenshots :

```
Inserted: Philadelphia Flyers - 2011
Inserted: Phoenix Coyotes - 2011

Custom Content: All Good

Conclusion :

The web scraping application developed for this project successfully achieved the objectives outlined in the assignment. Below are the key results and discussions regarding the implementation and performance of the scraping application:

1. Functionality:

The scraping application effectively extracts data from the provided URLs:

<https://www.scrapethissite.com/pages/ajax-javascript/#2015>

<https://www.scrapethissite.com/pages/forms/>

<https://www.scrapethissite.com/pages/advanced/>

Data from dynamic content rendered through JavaScript is successfully captured using the "requests" library, ensuring comprehensive data extraction.

2. Code Quality:

The codebase is well-structured, modular, and adheres to Python best practices. Clear separation of concerns is maintained with separate scripts for scraping individual pages (forms.py, advanced.py, etc.).

Logging is implemented to capture errors and provide insights into the scraping process for debugging purposes.

3. Error Handling:

Robust error handling mechanisms are in place to manage timeouts, network errors, and unexpected changes in website structure.

Errors encountered during scraping are appropriately logged to the scraper.log file, enabling easy identification and troubleshooting of issues.

4. Data Persistence:

Scraped data is efficiently stored in the MongoDB database, ensuring reliability and scalability.

Database schema design facilitates easy retrieval and manipulation of data for further analysis or application usage.

Duplicate data prevention is implemented to avoid redundant entries in the database.

5. Performance Optimization:

The application utilizes multi-threading to improve scraping performance by

concurrently executing scraping scripts.

Additional performance optimization techniques, such as parallel scraping or caching mechanisms, can be explored further to enhance efficiency and minimize server load.

6. Documentation:

Comprehensive documentation is provided, detailing setup, installation, and usage instructions for the scraping application.
